**HAL** is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers. L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

# **Dear Author**

Here are the proofs of your article.

- You can submit your corrections **online**, via **e-mail** or by **fax**.
- For **online** submission please insert your corrections in the online correction form. Always indicate the line number to which the correction refers.
- You can also insert your corrections in the proof PDF and email the annotated PDF.
- For **fax** submission, please ensure that your corrections are clearly legible. Use a fine black pen and write the correction in the margin, not too close to the edge of the page.
- Remember to note the **journal title**, **article number**, and **your name** when sending your response via e-mail or fax.
- **Check** the metadata sheet to make sure that the header information, especially author names and the corresponding affiliations are correctly shown.
- Check the questions that may have arisen during copy editing and insert your answers/corrections.
- Check that the text is complete and that all figures, tables and their legends are included. Also check the accuracy of special characters, equations, and electronic supplementary material if applicable. If necessary refer to the *Edited manuscript*.
- The publication of inaccurate data such as dosages and units can have serious consequences. Please take particular care that all such details are correct.
- Please **do not** make changes that involve only matters of style. We have generally introduced forms that follow the journal's style.
- Substantial changes in content, e.g., new results, corrected values, title and authorship are not allowed without the approval of the responsible editor. In such a case, please contact the Editorial Office and return his/her consent together with the proof.
- If we do not receive your corrections within 48 hours, we will send you a reminder.
- Your article will be published **Online First** approximately one week after receipt of your corrected proofs. This is the **official first publication** citable with the DOI. **Further changes are, therefore, not possible.**
- The **printed version** will follow in a forthcoming issue.

### Please note

After online publication, subscribers (personal/institutional) to this journal will have access to the complete article via the DOI using the URL:

http://dx.doi.org/10.1007/s10764-017-9960-2

If you would like to know when your article has been published online, take advantage of our free alert service. For registration and further information, go to: <u>http://www.link.springer.com</u>.

Due to the electronic nature of the procedure, the manuscript and the original figures will only be returned to you on special request. When you return your corrections, please inform us, if you would like to have these documents returned.

Abstract In a world increasingly dominated by human demand for agricultural prod-13ucts, we need to understand wildlife's ability to survive in agricultural environments. 14 We studied the interaction between humans and Javan slow lorises (Nycticebus 15*javanicus*) in Cipaganti, Java, Indonesia. After its introduction in 2013, chayote 16 (Sechium edule), a gourd grown on bamboo lattice frames, became an important cash 17crop. To evaluate people's use of this crop and to measure the effect of this increase on 18 slow loris behavior, home ranges, and sleep sites, we conducted interviews with local 19farmers and analysed the above variables in relation to chayote expansion between 202011 and 2015. Interviews with farmers in 2011, 2013, and 2015 confirm the impor-21tance of chayote and of bamboo and slow lorises in their agricultural practices. In 2015 22 chavote frames covered 12% of land in Cipaganti, occupying 4% of slow loris home 23ranges, which marginally yet insignificantly increased in size with the increase in 24chayote. Slow lorises are arboreal and the bamboo frames increased connectivity within 25their ranges. Of the sleep sites we monitored from 2013 to 2016, 24 had disappeared, 26and 201 continued to be used by the slow lorises and processed by local people. The 27fast growth rate of bamboo, and the recognition of the value of bamboo by farmers, 28allow persistence of slow loris sleep sites. Overall introduction of chayote did not result 29in conflict between farmers and slow lorises, and once constructed the chavote bamboo 30 frames proved to be beneficial for slow lorises. 31

#### Introduction

34 35

Preservation of high-quality forest habitats is vital for the conservation of global 36 biodiversity. Yet, in a world increasingly dominated by humans with their ever-37 growing demands for agricultural products, an understanding of wildlife's ability to 38 survive and even thrive in agricultural environments is increasingly important 39 (Bhagwat et al. 2008; Estrada et al. 2012, 2017; Stafford et al. 2016). To meet this 40 need, researchers have suggested new approaches to study biodiversity, integrating 41 agricultural matrices into conservation planning for the preservation of rare species that 42also occur outside of pristine environments (Cassano et al. 2014; Meijaard and Sheil 43 2008). Farming systems that are intercropped by hedgerows or living fences of trees 44 have often been regarded as vital contributors to alleviation of fragmentation (Michel 45et al. 2006). In Europe, where deforestation has been occurring for centuries, hedge-46rows are often the only habitat left for wildlife (Gelling et al. 2007), and have thus been 47well studied in the context of mammalian density, dispersal ability, and behavioral 48 ecology (Michel et al. 2007; Zhang and Usher 1991). Even for forest specialists, 49hedgerows have been shown to be important habitats, making up parts of forest 50dwelling animals' home ranges and as dispersal vectors (Schlinkert et al. 2016). For 51tropical mammals, such studies have lagged behind, but are now necessary as intact 52habitats disappear at an alarming rate. 53

Researchers often study tropical mammals, including primates, in "pristine" habitats, 54rather than in disturbed, modified, or anthropogenic habitats, with an idea that evolu-55tionary adaptations can be studied only in such contexts (Hockings et al. 2015). 56Increasingly, however, the importance of anthropogenic habitats to primate ecology, 57conservation, and evolution is recognized (Asensio et al. 2009; Estrada et al. 2017). For 58some species, agricultural landscapes may be beneficial not only to primates, but also to 59humans when primates control pests, pollinate flowers, or simply live peaceably 60 without damaging crops (Estrada 2006; Williams-Guillén et al. 2006). Although such 61 interactions are not always amicable, primates can show remarkable behavioral flexi-62 bility, including dietary and habitat switching, and changes in polyspecific interactions 63 (Moore et al. 2010; Morrogh-Bernard et al. 2014; Nowak and Lee 2013; Tisovec 2014), making the study of the long-term sustainability of such systems important for 65primate conservation. 66

Agroforestry systems, areas in which trees or shrubs are grown around or among 67 crops or pastureland, are one type of landscape in which humans and primates may 68 come together (Estrada et al. 2012). Considering mainly diurnal primates, Estrada et al. 69 (2012) defined a number of ways primates can be useful to these systems, benefits also 70offered by a number of nocturnal primates. Researchers have recorded the pollination 71of agricultural plants by nocturnal primates: Javan slow lorises (Nycticebus javanicus) 72in Java and greater slow loris (N. coucang) in Malaysia (Nekaris 2014; Wiens et al. 73 2006). Insect consumption, which is also likely to include agricultural pests, has been 74observed in agroecosystems among Javan slow loris in Java (Rode-Margono et al. 752015), Mysore slender loris (Loris lydekkerianus lydekkerianus) in India (Kumara et al. 76

64 Q3/Q2

Coexistence Between Humans and Javan Slow Lorises in West Java

2016; Nekaris and Rasmussen 2003), Milne-Edward's potto (*Perodicticus edwardsi*) in77Cameroon (Pimley et al. 2005), and by Dian's tarsier (*Tarsius dianae*) in Sulawesi78(Merker et al. 2005).79

Being able to survive in human-modified landscapes is not enough; a tolerance 80 between humans and primates must exist, in that humans do not trap primates for food 81 or pets, or harm them over conflicts for food resources (Lee 2010). Mantled howlers 82 (Alouatta palliata) can feed and persist well in shade coffee plantations if left undis-83 turbed by humans, including capturing them for the pet trade (Williams-Guillén et al. 84 2006). Additional management by humans may also be required, such as increasing 85 connectivity between planted trees to aid in travel or predator avoidance, such as was 86 observed in Brazil's cacao (Theobroma cacao) agroforests for Wied's marmosets 87 (Callithrix kuhlii) and golden-headed lion tamarins (Leontopithecus chrysomelas) 88 (Tisovec et al. 2014). Several macaque (Macaca spp.) populations also can persist 89 alongside humans, where being caught for pets or for the biomedical industry is a 90 looming threat (Shepherd 2010). 91

The island of Java, Indonesia, is one of the most densely populated areas on earth. 92Java is largely deforested, and most of the remaining 10% forest covers (parts of) the 93 numerous volcanoes on the island (Whitten et al. 1996). Forest has been replaced by a 94mosaic of cities and villages, agricultural land, cash-crop plantations, and forest planta-95tions, e.g., teak (Tectona grandis), Sumatran pine (Pinus merkusii), and rubber (Hevea 96 brasiliensis) (Nijman 2013). About 17% of the agricultural land on Java consists of 97 home gardens and agroforest, whose forest-like structure more or less mimics natural 98forest (Whitten et al. 1996), thus greatly increasing connectivity for many species. 99

Javan slow lorises, nocturnal primates endemic to Java, are characterized by fully 100 arboreal slow climbing locomotion (Nekaris 2014). As such, one would expect them to 101 be particularly vulnerable to habitat fragmentation where movement on the ground is 102often a requirement (cf. Mortelliti et al. 2013; Vaughan et al. 2007). Slow lorises in 103general, however, are adapted to life at forest edges where increased sunlight creates a 104dense network of branches (Chivers 1980). Studies in the village of Cipaganti, Java, an 105agroforest ecosystem with a particularly high density of this Critically Endangered 106 primate, show that slow lorises enter a sleep site at dawn, where they remain until dusk. 107As with most other primates (Anderson 1998), slow lorises do not use nests but instead 108 sleep on a branch or tangle of branches, curled in a ball or huddled against group mates, 109within their chosen sleeping tree (Nekaris 2003). Such sleep sites are generally dense 110and have been hypothesized to protect them from extreme temperatures and predators 111 (Nekaris 2014). As slow lorises are territorial, the sleep sites of a group (male-female 112pair and offspring) fall exclusively within their own home range. Bamboo stands 113comprise 96% of sleep sites for Javan slow lorises in Cipaganti, as well as substrates 114for feeding and avoiding ground movement (Nekaris 2014). Bamboo stands are used 115(and reused) as sleep sites daily by slow lorises. Typically, 20-40 bamboo sleep sites 116are present in each slow loris's home range (K. Nekaris, unpubl. data). 117

Cipaganti is characterized by shifts in agriculture, with the types of crops grown 118 depending on local economic trends. For example, in 2012, when tomatoes (*Solanum 119 lycopersicum*) were economically valuable, farmers heavily planted this crop. Similarly, 120 in 2013, farmers began growing a gourd, chayote (*Sechium edule*), and by 2015 it 121 became the crop of choice. Chayote, locally known as *labu*, relies on a network of 122 bamboo frames in order to grow (Fig. 1). These frames are erected at ca. 1.6 m in height 123

/04

## AUTHOR RIDS 6 PRO 0 5/2017

and can be up to 1 ha in size, and cover what would have been open ground with a 124network of chayote vines growing on the frames. Owing to the increasing interest by 125farmers in planting chayote, we noted an accelerated rate of cutting of bamboo, 126possibly impeding on the survival of the Javan slow lorises. Here, we examine the 127impact of this new agricultural development on the behavior of slow lorises by 128addressing five questions. 1) Did farmers' perceptions of slow lorises, slow lorises 129perceived roles as consumer of agricultural pests and the importance of chayote to 130 farmers change over the study period? We assessed this through informal interviews 131with farmers over the period 2011 - 2015. 2) Did the amount of land planted with 132chayote change, and did chayote frames make up a significant proportion of slow loris 133home ranges? We assessed this by measuring the proportion of land allocated to 134growing chayote in 2014 and 2015, as well as measuring the proportion of the slow 135loris home range comprising chavote, also for 2014 and 2015. 3) Did slow loris home 136range sizes change or move position? We assessed this for 2014 and 2015 through 137 direct observations. 4) How did slow lorises behave in and around chayote frames? We 138assessed this through behavioral observations in 2012 through 2016. 5) Did cutting 139bamboo for chayote affect availability of slow loris bamboo sleep sites? We assessed 140this in 2016 by measuring the presence and intactness of bamboo sleep sites at differing 141altitudes that had been used in the period 2013-2015. 142

### Methods

143

144

### **Study Site and Its Changing Farming Practices**

This study forms part of a long-term community conservation project to protect Asia's 145 slow lorises and other imperilled nocturnal animals via ecology, education, and 146

**Fig. 1** Photographs of chayote frame structure in the Cipaganti area. **a** View from below a fully covered chayote frame. **b** View from above a chayote frame, built as cover, over a farmer's coffee plantation. Photos by Kathleen Reinhardt.

Coexistence Between Humans and Javan Slow Lorises in West Java

empowerment (Nekaris 2016). We conducted the study in an area of ca. 60 ha at the 147 outskirts of the village of Cipaganti, Cisurupan, Garut Regency, West Java, Indonesia 148(7°16'44.30"S, 107°46'7.80"E, 1200 m asl) (Fig. 2). Cipaganti is home to ca. 3000 149people, living at a density of 135 people/km<sup>2</sup> (Nekaris 2016). The village is located at 1501345 m asl on Gunung Puntang, a mountain that is a part of the Java-Bali Montane 151Rain Forests ecoregion. The climate is everyet, with a mean annual precipitation 152exceeding 2500 mm. The habitat around Cipaganti is a mosaic of traditional gardens, 153where local farmers practice an annual perennial rotating crop system. This system 154consists of a variety of crop formations, with tall trees planted in rows along farm 155property boundaries, or interspersed between crop types (Reinhardt et al. 2016). In our 156study site, slow lorises heavily use certain plants including string bamboo (Gigantochloa 157atter), clumping bamboo (G. pseudoarundinacea), giant bamboo (Dendrocalamus 158asper), cajeput tree (Malaleuca leucadendra), red fairy duster (Calliandra calothyrsus), 159green wattle (Acacia decurrens), avocado (Persea americana), and Indonesian mahog-160any (Toona sureni) (Rode-Margono et al. 2014). Within the village of Cipaganti, 161agricultural production provides the main source of household income, yielding crops 162such as tea (Camellia sinensis), coffee (Coffea robusta), chayote (Sechium edule), carrot 163(Daucus carota), white cabbage (Pieris brassicae), tomato (Solanum lycopersicum), 164cassava (Manihot esculenta), and potato (Solanum tuberosum). 165

Chayote is a medium- to high-altitude crop (300-2000 m asl) that requires a high 166relative humidity of around 80-85%, high annual precipitation of ≥1500 without a 167marked dry season, and 12 h of daylight to initiate flowering. The temperature should 168be between 13 and 21 °C; temperatures below 13 °C damage small and unripe fruits 169whereas temperatures above 28 °C lead to excessive growth, loss of flowers, unripe 170fruit, and ultimately reduced production (Saade 1996). Cipaganti matches these condi-171tions extremely well. The Garut Regency in which Cipaganti is situated is an important 172grower of chayote, both in absolute and relative terms, and the area set aside for 173growing the crop in Garut increased from 188 ha in 2012 (22% of the provincial total) 174

![](_page_9_Figure_5.jpeg)

Fig. 2 Location of Cipaganti in West Java, Indonesia.

K. A. I. Nekaris et al.

to 360 ha in 2015 (33% of the provincial total). Production in 2015 was 14,499 t/yr. (cf.175Morton 1981). If both the official government figures and the estimates from the176farmers in Cipaganti are correct then the wider Cipaganti area (which stretches beyond177our study area) is responsible for some 60% of the regency's chayote production,178suggesting that this crop will be around at least for the foreseeable future with a179180180

#### **Interviews with Informants**

181

In June 2011, June 2013, December 2015, and June 2016 we held informal interviews 182 (Newing 2011) with opportunistically selected key informants with farms situated 183within the home ranges of collared slow lorises (6 informants in 2011, 16 in 2013, 184 and 17 in 2015). Most informants lived in the village and were long-time residents (and 185typically born here or had moved into the area during childhood); in addition, we 186 interviewed five informants from neighbouring villages. In 2011 and 2013 the 187 conversations focused on the importance of slow lorises to the village, from a 188 cultural, natural, and economic perspective. Given that chayote was not of partic-189ular importance at that time, farmers did not single out this crop but discussed it in 190the context of general agricultural crops. In 2015 the topic of discussion was 191similar to that in 2011 and 2013 but now much of it centered on chayote; given the 192dominant role of chayote in the agricultural landscape and the village economy, 193informants initiated discussions on this topic. 194

We held informal interviews in Bahasa Indonesia, the national language that is very 195widely spoken on Java (Sneddon 2004), repeating key concepts in Bahasa Sunda, the 196 regional language spoken in this part of the island. Informal interviews were open, 197 allowing informants to talk freely about slow lorises, their significance in culture or the 198 beliefs surrounding them, and their role in the agricultural system. To ensure indepen-199dence of data, we interviewed informants individually; other members of the commu-200nity sometimes were present, but we used only the responses of the informant in 201analysis. At the end of each interview, we repeated key points to ascertain whether 202we captured the essence of the informant's opinions/expressions correctly. Informants 203did not receive gifts or money for their participation. 204

We asked informants to share any knowledge they had of slow lorises, touching on 205any topic they felt to be relevant, without any constraint placed on them by us (Bernard 2062011; Puri 2011). We converted these conversations into freelists, from which we 207extracted the frequency of occurrence for each item, i.e., what proportion of informants 208mentioned topics such as "slow lorises are useful for pest control," "bamboo," or 209"chayote," and the rank for each item, i.e., whether they mentioned early on or at 210the very end of the interview, on a scale from 1 to 4 (Puri 2011). This procedure 211allowed us to check whether these topics were locally salient or meaningful. 212Salience was quantified by calculating Smith's  $S (S = ((L - R_i + 1)/L)/N$ , where 213L is the number of distinct items listed by the informants,  $R_i$  is the rank of item J 214in the list, and N is the number of lists/informants in the sample). Smith's S ranges 215from 0 to 1, with topics having values close to 1 being the ones that were 216mentioned by most informants early on in the conversation, and topics having 217values close to 0 being the ones that few informants mentioned, and if so, often 218late in the conversation (Puri 2011). 219 Coexistence Between Humans and Javan Slow Lorises in West Java

#### **Slow Loris Behavioral Observations**

220

248

To examine the presence of chavote in slow loris home ranges, we surveyed the 221study site to locate each chayote frame, measuring their perimeters and monitoring 222change in their presence from January 2014 to May 2015. To examine the 223behavior of slow lorises in relation to chavote frames, we analyzed behavioral 224data collected on collared slow lorises from the first time we saw them enter a 225chayote frame in June 2014 until June 2016. Because Javan slow lorises live in 226stable unimale-unifemale pairs with almost 100% range overlap and share sleep 227sites (Nekaris 2014), we examined the impact of chayote frames on social groups 228rather than individuals. We focus on adult individuals belonging to eight focal 229 unimale-unifemale social pairs (Table I). After catching the slow lorises by hand, 230we equipped them with 19-g VHF collars (PIP3, Biotrack, Wareham, UK). With 231the assistance of local field trackers, we located collared individuals using an 232antenna (Lintec flexible, Biotrack, Wareham, UK) and a receiver (Sika receiver, 233Biotrack, Wareham, UK), and recorded their location every 15 min using a 234handheld GPS unit (GPS62s, Garmin International, Olathe, KS, USA). For direct 235observations we used head torches (HL17 super spot, Clulite, Petersfield, UK) 236fitted with a red filter. To observe the behavior of slow lorises in chayote, we 237followed slow lorises for 3199 h between 17:00 and 05:00 h, from January 2014 238to December 2015 (a mean of  $13 \pm 7$  nights per month). We used all-occurrences 239sampling to record each instance one of the 16 focal lorises entered chayote using 240a modified version of the Rode-Margono et al. (2014) behavioral ethogram. 241Chayote frames are very dense and often when slow lorises enter these frames 242they are out of sight until they reemerge into a tree or bamboo. To see if slow 243lorises altered their home range use between 2014 and 2015, we computed the 244home ranges of the eight focal pairs based on 5851 locations using the 95% 245minimum convex polygon (MCP). We performed all GIS work using R (R 3.0.2, 246adehabitatHR package) (R Core Team 2013). 247

### **Sleep Sites**

We defined a bamboo sleep site as the stand of bamboo in which a slow loris social 249group slept. A single stand can contain >100 stems or culms of bamboo. During one 250sleeping period, slow lorises sometimes move from one stem to another, making the 251stand the unit of analysis. We recorded location of bamboo sleep sites of the eight focal 252pairs of slow lorises once per week from January 2013 (before the appearance of 253intensive chayote) to December 2015, georeferencing each site using a handheld GPS 254unit. To measure sleep site reuse we plotted the points collected during 2013, 2014, and 2552015 in ArcGIS version 10.3. We created a 5-m buffer around each point to 256account for standard GPS error in the area, and then counted each point within 257overlapping buffers as a single reused sleep site. In June 2016, we returned to 258the locations of 225 unique bamboo sleep sites; each site revisited fell only in 259the range of one social pair. In particular, we examined: if the bamboo sleep site 260still stood in 2016; if yes, had it been cut, including number of whole and cut 261stems remaining and the number of newly sprouting stems; if no, we recorded 262what was there instead of the bamboo. 263

### AUTHORARIS BEPRIN - 29/05/2017

t1.1 **Table I** Social pairs of 16 collared Javan slow lorises and associated home range sizes in Cipaganti, West Java, Indonesia from January 2014 to December 2015

We estimated home range sizes from 95% minimum convex polygons based on observed locations (N = 5851)

#### **Statistical Analysis**

Behavioral, sleep site, and ranging data did not deviate significantly from a normal 265distribution. To investigate the influence of the chavote production on slow loris, we 266tested whether the percentage of chayote frame could explain observed variation in 267individual home range size. We fitted a multiple linear regression to the data, with the 268percentage of chayote frame within a home range and the year as the explanatory 269variables. We conducted the analyses in R. We present descriptive statistics of the 270characteristics of bamboo sleep sites, reporting the mean and  $\pm 1$  standard deviation, 271with P set at 0.05. 272

### **Ethical Note**

We conducted all animal research in adherence with RISTEK (Indonesian Ministry of<br/>Science and Technology), as well as ethical guidelines provided by the Association for<br/>the Study of Animal Behaviour; Oxford Brookes University Animal Ethics Sub-<br/>committee granted our research approval. For the interviews we followed the ethical<br/>guidelines proposed by the Association of Social Anthropologists of the United<br/>Kingdom and Commonwealth and that the University Research Ethics Committee of<br/>Oxford Brookes University approved.274275<br/>276<br/>277276277<br/>278<br/>279278279<br/>280280

#### Results

### Farmers' Perceptions of Slow Lorises, Pests, and Crops

In 2011 one out of six informants indicated that slow lorises were allies to farmers as they consumed pest insects, but they mentioned this concept only late in the conversation. In 2013 many more informants (13/16) were aware that slow lorises consumed agricultural pests and they brought up this topic earlier on in the conversation. The

273

281

282

Coexistence Between Humans and Javan Slow Lorises in West Java

**AUTHOR'S PROOF** 

situation was similar in 2015 when 15/17 informants mentioned it. Quantitatively, 287 salience, as measured by Smith's *S* of "slow lorises and pest control," started at a low 0.04 in 2011, and then increased to 0.69 in 2013 and 0.72 in 2015. 289

The knowledge of the importance of bamboo for slow lorises was high in 2011, with 290 five out of six informants mentioning it. This knowledge remained high in 2013 (14/16) 291and 2015 (13/17), with some informants mentioning it early on in the conversation and 292others later on. Quantitatively, Smith's S of "slow lorises and bamboo" was 0.54 in 2932011, 0.49 in 2013 and 0.53 in 2015. Chavote as a crop was not significant enough 294for the informants to mention it in 2011 and 2013. In 2015, all informants 295mentioned chavote as a crop, two-thirds early on. As such salience of chavote 296 was zero in 2011 and 2013 but Smith's S equaled 0.83 in 2015, surpassing that 297of all the other topics they discussed. 298

The importance of chavote as a crop led farmers we interviewed to claim that 299chayote was probably the most important cash crop in the area by December 2015. It 300 then had a market value of Rp 5000-6000 (US\$0.35-0.42) per kg. On average five 301trucks of differing sizes collected chayote daily, with a capacity to carry 4-7 metric 302 tonnes per truck. Informants estimated that some 25 t of chayote was produced a day in 303 the wider Cipaganti area, which is larger than the area where we study the slow lorises. 304Although initially chayote farmers organized their businesses independently, by early 305 2016 a chavote-growing cooperation was started in which 50 of the largest chavote 306 farmers joined forces to share costs, logistics, knowledge, and profits. 307

To create a chayote frame, which in our study area on measures a mean of  $1500 \text{ m}^2$ , 308 or 0.15 ha, 150 bamboo stems ca. 2 m tall are required for the main vertical supports 309 and 120 lengths of bamboo measuring 6 m each are needed for the main horizontal 310 supports. Farmers we interviewed reported that up to 30% of the poles need to be 311 replaced every 6 mo, a cost that must be considered when investing in chayote. Three 312 species of bamboo occur frequently in Java, but differ in price according to our 313 interviews, including string bamboo at Rp 5000 (US\$0.35) per stem, giant bamboo at 314 Rp 9000 (US\$0.64) per stem, and clumping bamboo at Rp 20,000 (US\$1.41) per stem. 315At the beginning of the chavote boom our interviewees reported that they sourced most, 316 if not all, this bamboo locally but by 2015 farmers ordered truckloads of bamboo from 317 the north coast of Central Java, i.e., some 250 km to the east, to meet their demands. 318 Some farmers in our area used more durable concrete poles instead of bamboo ones as a 319 longer-term option, but these are far more costly at Rp 30,000 (US\$2.12) for a 2-m 320 length of pole. Using mean figures, the initial investment for a bamboo chayote frame, 321 with labor costs, and plants amounts to some US\$500. After 4 mo farmers can harvest 322 the first fruits, and from then on production is more or less continuous. With an annual 323 yield of ca. 40 t/ha (Morton 1981) the break-even point in terms of financial investment 324 is reached well within the first year. 325

#### Chayote in the Slow Loris Landscape

Planting of chayote began in the study area in early 2014 with just a few small frames.327By July 2014, many farmers had planted chayote; we recorded 34 chayote frames328encompassing an area of 1.6 ha. The numbers increased, with an additional 58 frames329encompassing 2.5 ha planted by November 2014. By April 2015 we recorded 145330chayote frames representing a total of 7.2 ha, i.e., 12% of the study area. This represents331

326

338

352

2.7% (range 0–5.6%) of the social pairs home ranges in 2014 and and 3.9% (range 0– 13.0%) in 2015 (Fig. 3).

In 2014, the mean slow loris home range size was 7.1 ha  $\pm$  2.0. In 2015, the mean 334 was 6.6 ha  $\pm$  1.2 (Table I, Fig. 3). Over both years the mean was 7.5 ha  $\pm$  1.1. Home 335 range size was not affected by the year or percentage of chayote frame ( $F_{2,13} = 1.75$ , 336 P = 0.21, N = 16). 337

#### Behavior of Slow Lorises in Chayote

We first recorded use of chayote frames by two social pairs of slow lorises (LU, SI) in 339 June 2014. By October 2014, we had also observed pairs SH and OE using the frames. 340 By June 2015, we had recorded all social pairs regularly using chayote frames; the last 341 pair to use the frames was MA with the first record dating to January 2016. Slow lorises 342 used the frames as if they were a normal bamboo substrate, moving fluidly across the 343 bamboo poles to reach rows of trees on opposite ends of farmers' fields. Chayote 344frames are very dense and difficult for a human observer to move under, and thus we 345could only record 211 all-occurrences sample points of slow loris behavior in the 346 chayote. Slow lorises used chayote most frequently for traveling (68%), followed by 347 foraging for or feeding on insects (22%), allogrooming (6%), resting (2%), and other 348 (2%). We could not identify insects to the species level, but noted that slow lorises 349consumed flying insects that they caught with their hands as well as those that they 350orally removed from the chayote frames. 351

#### **Slow Loris Sleep Sites**

We recorded the social pairs in a bamboo sleep site a total of 1350 times, comprising 353 514 unique locations, 211 of which had been reused (2013, N = 340 with 95 reused; 3542014, N = 444 with 53 reused; 2015, N = 566 with 89 reused). Slow lorises used three 355 species of bamboo, with 8 sleep sites consisting of clumping bamboo, 52 consisting of 356 giant bamboo, and 454 consisting of string bamboo (Fig. 4). In 2016, we revisited 225 357 bamboo sleep sites used in the period 2013–2015 comprising a mean of  $28 \pm 21$ 358 bamboo sleep sites unique to each pair (Table II) and found that 89.3% of sleep sites 359 (N = 201) remained and were still being used by slow lorises. Eleven sleep sites had 360 been replaced by chayote, 11 were replaced by bare ground, and 2 had disappeared as a 361result of landslides. The remaining 201 sleep sites ranged in size from 1 to 101 stems, 362 with a mean of  $35.5 \pm 24.5$  stems per bamboo stand. Only 3 of these stands remained 363 fully intact, with 198 containing cut stems. The mean number of cut stems per bamboo 364stand was  $19.9 \pm 15.8$ , with the mean number of newly sprouting stems being 365  $7.57 \pm 10.9$ . Social pairs differed in the number of sites destroyed, cut stems, and 366 new sprouting stems (Table II). 367

### Discussion

Farmers in Cipaganti increasingly recognized the importance of slow lorises in the 369 control of agricultural pests, and chayote became more important over time. In 2015 370 some 12% of the study area was used to grow chayote and on average 4% of the slow 371

Coexistence Between Humans and Javan Slow Lorises in West Java

![](_page_15_Figure_3.jpeg)

**Fig. 3** Chayote frames and 95% MCP of Javan slow lorises social pairs (N = 8) over the study area in Cipaganti, Java, Indonesia in 2014 and 2015. The names of the social pairs are indicated at the top.

lorises' home range comprised chayote frames. Range size of slow lorises only372marginally increased over time and remained stable in terms of their geographic373position; i.e., no home range size shifts were recorded). Over time, Javan slow lorises374started using the chayote frames, mostly for traveling but also for feeding and social375interactions. Although cutting for chayote disturbed sleep sites, the fast growing376bamboo meant that animals still had more than adequate places to sleep.377

Researchers have heralded agroforestry as a positive step toward achieving coexis-378 tence between wildlife and farmers. Chavote is as a useful vine in such forests, 379 providing shade for lower strata plants (Clerck and Negreros-Castillo 2000). Humans 380 domesticated chayote centuries ago and worldwide have used it for its economic and 381 cultural value (Lira et al. 2002). Chayote has replaced other more traditional agrofor-382 estry practices no longer viable on Java (Iskandar et al. 2016). In Cipaganti, it provides 383 excellent economic services, and requires less intensive farming practices compared to 384 root vegetables, being easy to harvest and not requiring the use of pesticides (Morton 385 1981). People introduced chayote into the "traditional bamboo garden" (kebun 386 tatangkalan) landscape of Cipaganti, where the crop has partially persisted on the basis 387 of deep cultural affinities to this ancient farming practice (Abdoellah et al. 2015). 388 Together with bamboo and other planted trees, chayote frames and the associated 389 climbers provide a form of living fence or canopy corridor for slow lorises and other 390 wildlife, including rare species such as Javan leopard (Panthera pardus melas), Javan 391ferret badger (Melogale orientalis), banded linsang (Prionodon linsang), and binturong 392(Arctictis binturong). Such a system, as opposed to monoculture plantation, seems to 393

allow this mammalian diversity to persist in Cipaganti while providing an excellent 394 economic commodity to local people. 395

Despite the increase in growth of chayote, farmers we interviewed showed sensitiv-396 ity toward slow lorises, and did so increasingly over the study. In particular, more 397 farmers recognized the role of slow lorises as pest controls and realized that bamboo 398 species are important plants for slow lorises. Since 2012, we have disseminated 399 information about slow lorises and other native species to farmers through newsletters 400and other events and by providing classes to their children (Nekaris 2016). We also 401distributed materials such as leaflets, umbrellas, and t-shirts, emphasizing the role of 402 slow lorises in the ecosystem. Such modes of outreach have proven successful in 403 conservation education and community outreach programs (Evans et al. 1996; Vaughan 404 et al. 2003; Walter 2009). Indeed, Waylen et al. (2010) suggest that integrating the 405 community into conservation programs is a key way to change attitudes and allow a 406 conservation project to succeed. Human attitudes toward Javan slow lorises differ in 407 adjacent areas, including an unsustainable pet trade in the species; thus any conserva-408tion of them in human-modified landscapes must include a human outreach component 40905 (Nijman and Nekaris 2014). 410

Although chayote frames comprised >3% of slow lorises' home ranges, home range 411 sizes of the social pairs remained stable and completely within the agroforest matrix. 412 Chayote frames provided a substrate to move across open fields that had been previ-413ously planted with low-growing plants treated with pesticides, such as carrots and 414 cassava. Chayote frames appeared to offer the slow lorises a network of substrates that 415shielded them from predators and contained an abundance of insects. Researchers have 416previously reported the ability to maintain home ranges completely within for wood 417 mice (Apodemus sylvaticus), golden-headed lion tamarins (Leontopithecus 418chrysomelas), and three-toed sloths (Bradypus variegatus) (Oliveira et al. 2011; 419Rosalino et al. 2011; Vaughan et al. 2007). Wood mice can exploit planted olive 420groves, and also showed a preference for areas with understory; these preferences were 421

interpreted as improving female fitness and avoiding predators (Rosalino et al. 2011). 422Golden-headed lion tamarins and three-toed sloths could survive with their home 423 ranges completely in agroforests (Oliveira et al. 2011; Vaughan et al. 2007). 424Although tamarin home ranges were smaller than in primary forest, animals were 425 heavier in size and reproduced well. Tamarins relied largely on planted jackfruit 426 (Artocarpus heterophyllus). In the case of three-toed sloths, they integrated human-427 planted living fences into their home ranges. A similar scenario can be observed in 428 Javan slow lorises, whose plant consumption of exudates and nectar is completely from 429human-introduced species, and whose movements rely heavily on human-planted 430substrates (Rode-Margono et al. 2014). Unlike these taxa, however, slow lorises eat 431 mainly gum, insects, and nectar, meaning that resources they consume do not put them 432 in competition with humans, and even have the capacity to help humans. 433

The chayote bamboo frames provided a new substrate network that slow lorises used 434for both foraging and moving across their fragmented landscape. Indeed, the full range 435of behaviors exhibited by slow lorises in chayote in this study mirror the general 436behavioral ethogram reported Rode-Margono et al. (2014) for the same population 437 [foraging and feeding 22.4% in this study vs. 31% in Rode-Margono et al. (2014); 438resting 2% vs. 33%; traveling 68% vs. 14%; grooming 6% vs. 7%; other 2% vs. 13%). 439The connectivity provided by chayote frames and the high number of insects available 440 because of the absence of pesticides can help explain the higher proportion of feeding 441 and traveling. The rapid incorporation of the frames into the slow loris behavioral 442 repertoire is an example of their flexibility and ability to survive in human-modified 443 landscapes, at least for the period of our study. Indeed, slow lorises conform to Nowak 444 and Lee's (2013) statement that the ability to expand niche breadth via resource 445 switching, including substrate choice and modification of diet, is key to withstanding 446 the risks of anthropogenic habitat modification. 447

The harvesting of the fast-growing bamboo led to the disappearance of some 10% of 448 bamboo sleep sites. Most (98%) of the remaining bamboo sleep sites were affected by 449the harvesting practices for chayote but enough bamboo stems remained for the slow 450lorises to keep using bamboo stands as sleep sites. Bamboo is by far the most important 451sleep site for slow lorises in Cipaganti, comprising 96% of all sites observed since 2012 452(K. A. I. Nekaris, unpubl. data). Throughout their range, slow lorises never use tree 453holes and rely on forms of closed substrates for sleeping including dense shrubs, palms, 454lianas and bamboo stands (Kenyon et al. 2014; Wiens 2002). Pygmy lorises 455(Nycticebus pygmaeus) sleep on high clumps of terminal tree branches with a prefer-456ence for very dense edge forests (Streicher and Nadler 2003). Slow lorises have been 457never been observed to sleep on the ground and are typically found at 1.8-35.0 m 458height (Wiens 2002). The maintenance of bamboo shrubs in Cipaganti is clearly vital 459 for their perseverance in this human-dominated landscape, and the current human 460practice of cutting only parts of bamboo stands is for the time being allowing this 461 persistence. 462

We agree with Sheil and Meijaard (2010) in their description of the "tainted nature defaultion," whereby conservationists neglect the value of human-modified habitats. 464 Researchers in temperate regions have long recognized the value of these ecosystems 465 (Cassano *et al.* 2014), and it would be prudent for those working in tropical and 466 subtropical regions to follow suit. Studying a difficult to observe, cryptic nocturnal 467 primate like the Javan slow loris in a human-modified landscape has several 468

Coexistence Between Humans and Javan Slow Lorises in West Java

advantages. While experiencing the effects of rapid environmental change, the Javan 469slow loris has created an opportunity for researchers to understand their ecological, 470behavioral, physiological, and cognitive capacities (Hockings et al. 2015). Studying 471 flexibility in these situations may shed light on the evolution and adaptability of extant 472 strepsirrhine and extinct early primates. Species level evolutionary history plays an 473important role in the response to novel environments (Hendry et al. 2011). An 474**Q6** organism's response to human disturbance can be categorized as addressing novel 475predators, using novel resources, avoiding novel abiotic threats, and acclimating to 476 fluctuating spatiotemporal conditions (Sih et al. 2011). In the case of the Javan slow 477 loris, our findings highlight their behavioral flexibility in a human-modified landscape. 478 Recent IUCN Red List assessments have determined that >50% of primates face 479extinction (Estrada et al. 2017). With the rapid change in habitat transformation for 480 agricultural practices sweeping the tropics, we feel it is urgent to understand the 481behavior of primates in such landscapes, and to find ways they can continue to share 482these spaces with humans. 483

Acknowledgments We thank the villagers in Cipaganti and other parts of West Java for their time and 484 patience in sharing their views and knowledge unreservedly with us. We thank Indonesia RISTEK and the 485regional Perhutani and BKSDA for authorizing the study. ### AUTHOR QUERIES

### AUTHOR PLEASE ANSWER ALL QUERIES.

- Q1. Affiliation 1 has been set as the corresponding affiliation, please check if correct.
- Q2. The citation "Morrogh-Bernard 2014" has been changed to "Morrogh-Bernard et al., 2014" to match the author name/date in the reference list. Please check if the change is fine in this occurrence and modify the subsequent occurrences, if necessary.
- Q3. Ref. "Tisovec 2014" is cited in the body but its bibliographic information is missing. Kindly provide its bibliographic information in the list.
- Q4. The citation "Pimley et al. 2006" has been changed to "Pimley et al., 2005" to match the author name/date in the reference list. Please check if the change is fine in this occurrence and modify the subsequent occurrences, if necessary.
- Q5. The citation "Nijman and Nekaris 2015" has been changed to "Nijman and Nekaris, 2014" to match the author name/date in the reference list. Please check if the change is fine in this occurrence and modify the subsequent occurrences, if necessary.
- Q6. The citation "Hendry et al. 2001" has been changed to "Hendry et al., 2011" to match the author name/date in the reference list. Please check if the change is fine in this occurrence and modify the subsequent occurrences, if necessary.
