ABSTRACT

Ethnopharmacological importance: The use of medicinal plants for treatment, cure and prevention of diseases has been described by many people since time immemorial. Because of this use, commercial and scientific interests have emerged, making it necessary to realize ethnobotanical surveys of medicinal plants species, which is important for subsequent chemical and pharmacological bioprospections.

Aim of the study: This study aimed at surveying, identifying, cataloging and documenting the medicinal plants species used in the Valley of Juruena, Northwestern Mato Grosso, Legal Amazon Brazil for the treatment of various human diseases, as well as assessed the species of interest for bioprospecting potential.

Materials and methods: Informants were interviewed using semi-structured form to capture information on socio-demographic and ethnopharmacological data of medicinal plants such as vernacular name, uses, geographic origin, habit, form of preparation and part used. Results were analyzed using descriptive and quantitative means: indices of use-report (Ur) and informant consensus factor (ICF), for the selection of plant species with therapeutic potential.

Results: Three hundred and thirty two (332) plants species belonging to 90 families were reported for medicinal purposes and totaling 3973 use-reports were reported by 365 (92.9%) of the people interviewed. Asteraceae (32.2%), Fabaceae (26.7%) and Lamiaceae (24.4%) families were the most represented, with majority being species native (64.45%) to Brazil. Leaves (64.5%) were the part of the plant most used and infusion (45.7%) was the most utilized form. Gastrointestinal disorders followed by respiratory complaints topped the list of use-reports. The native or naturalized plants with the highest use reports in the order of decreasing absolute frequency per each emic-category are *Cymbopogon citratus* (DC.) Stapf (104), *Mentha pulegium* L. (94), *Arrabidaea chica* (Humb. & Bonpl.) B. Verl. (97), *Alternanthera brasiliiana* (L.) Kuntze (71), *Baccharis crispa* Spreng (57), *Phyllanthus niruri* L. (48), *Gossypium barbadense* L. (44), *Solidago microglossa* DC. (40) and *Bauhinia forficata* L. (20). And the most cited exotics are: *Chenopodium ambrosioides* L. (151), *Aloe vera* (L.) Burm. f. (89) and *Rosmarinus officinalis* L. (72). In some cases, high ICF values were found, which reflects high degree of homogeneity of consensus among informants in this region on medicinal plants.

Conclusion: The population of Valle of Juruena makes use of a wide array of medicinal plants distributed in all use categories with predominance of those use in the treatments of gastrointestinal and respiratory

ailments. The therapeutic potential of some of the species of medicinal importance extensively utilized by the population of the region have been scientifically validated, and are therefore promising prototype of new drugs. However, there are some of these species whose ethnomedicinal uses are yet to be scientifically verified and thus constitute an unexplored terrain for future biological/pharmacological studies.

1. Introduction

The Amazon rainforest also known as “Amazônia”, ‘Selva Amazônica’, ‘Hileia Amazônica’, Rain Forest and Amazon Equatorial Forest is present in nine countries of South America (Brazil, Peru, Colombia, Venezuela, Ecuador, Bolivia, Guyana, Suriname and French Guiana) occupying an area of 5,500,000 km², with most part found in the Brazilian territory (60%) (Rodrigues et al., 2014).

In Brazil, the Amazon accounts for 49.29% (4,196,943 km²) of the territory, covering seven states of the Northern Region (Amazon, Pará, Tocantins, Rondônia, Acre, Amapá and Roraima), one of the Midwest (Mato Grosso) and one of the Northeast (Maranhão). For the purposes of social and economic development of the Amazon region, the Brazilian government in 1996 introduced the concept of Legal Amazon which holds 12.4% of the Brazilian population (Michael, 2007).

The Amazon rainforest is a biome characterized, like all tropical forests, by its high biodiversity. Around 1100 tree species were censed in an area of 0.25 km², which is around as many species found in 4.2 × 106 km² of temperate forests of Europe, Asia and North America (Wright, 2002). In addition, previous ethnopharmacological field-studies with local Amazonian populations have identified several medicinal species popularly used for the treatment of a range of diseases (Rodrigues, 2006), while other studies showed promising activities in preliminary *in vitro* assays (Kloucek et al., 2007).

The Amazon rainforest is the most extensive equatorial forest in the world and represents the largest reservoir of plant and animal species, hosting an estimated one-quarter of all terrestrial species (Rodrigues et al., 2014). Besides having the largest plant

and animal biodiversity in the world, with approximately 25% of all terrestrial species (Rodrigues et al., 2014), the Amazon is a cultural complex, the bearer of a traditional set of values, beliefs, attitudes and ways of life that have shaped the social organization and system of knowledge, practices and uses of natural resources, that was previously predominantly indigenous. New values and cultural practices have been incorporated to the existing ones by the colonizers and settlers, mainly Portuguese and Spanish, with some African, Asian and Semitic contribution, in addition to new values contributed by the northeastern migrants and, more recently from various regions of Brazil, especially migrants from the South and Southeast Regions (Benchimol, 2009). With this multi-diversity of peoples and nations, the Amazon is home to a significant number of indigenous and traditional peoples including rubber tappers, chestnut tree collectors, riverine dwellers, babassu collectors, among others, that give prominence to its cultural diversity (Benchimol, 2009).

Here we report on an ethnopharmacological field-study conducted in the Valley of Juruena, a little studied area within the Amazon rainforest. The ethnobotany of this region was of particular interest to us, because, despite being located in one of the biodiversity rich environments, there is lack of comprehensive studies regarding the uses of medicinal plants by the local population, however, there is a report on the pharmacological activity of a medicinal plant species from this region (Mafioletti et al., 2013).

The present study focused on a quantitative ethnobotanical field-work through interviews of Valley of Juruena population and the analysis of the data obtained. Additionally we evaluated the most important medicinal plants of this region using information in the specialised literature in the area. The rationale for using

these plants by the population of Valle do Juruena is also discussed.

2. Methods

2.1. Description of the study area

Valley of Juruena Region is located in the northwestern part of Mato Grosso State of Brazil. It is divided into seven municipals (Juína, Aripuanã, Brasnorte, Conilza, Castanheira, Cotriguaçu and Juruena) and located between $11^{\circ}22'$ – $09^{\circ}24'$ – $10^{\circ}10'$ – $12^{\circ}9'$ – $09^{\circ}24'$ – $11^{\circ}07'$ – $09^{\circ}57'$ – $10^{\circ}20'$ S and $58^{\circ}44'$ – $59^{\circ}27'$ – $57^{\circ}58'$ – $59^{\circ}01'$ – $58^{\circ}36'$ – $58^{\circ}24'$ – $58^{\circ}30'$ W, respectively as shown in Fig. 1 (Mato Grosso, 2012).

The population of the Valley of Juruena Region counts with 139,524 inhabitants, which represents 4.6% of the total population of Mato Grosso, with a high percentage of migrants coming from the south-central part of Brazil. The area is characterized by ecological diversity wholly represented by the biome of the Amazon, the largest rainforest in the world, covering a total area of 111,849.70 km² (IBGE, 2013). Although the area was traditionally seen as a relatively homogeneous biome today, the idea prevails that it is a mosaic of different ecosystem harboring heterogeneous community, in both composition and diversity (Prance and Lovejoy, 1985; Ferreira, 2001). The climate is hot and humid equatorial, with two months of drought from June to July, and the annual rainfall is 2750 mm on average, with temperature varying between 4 and 40 °C (Ferreira, 2001).

The 7 municipals are regarded as agricultural frontiers of Mato Grosso, i.e. they have their economy based on agricultural expansion. The economy of the whole region is largely based on the rural sector, with agriculture, timber industry as well as gold and diamond mining as the main income sources (Mato Grosso, 2012).

2.2. Data collection

2.2.1. Sampling design

While the large part of ethnobotanical field studies focused on expert knowledge (Heinrich et al., 2009), in the present study we focused on the average knowledge and attitude towards medicinal plants, self-medication, and therapeutic choices by the population of Valley of Juruena. Therefore, we needed to collect a sufficiently large, randomly selected and unbiased sample using sampling method termed "probability sampling" or "random sampling" by Bolfarine and Bussab (2005).

We used probabilistic planning considering a simple and stratified randomized sampling method (Bolfarine and Bussab, 2005; Scheaffer et al., 2006). Calculation of estimated total sample size for the whole Region as well as the micro-areas was realized as

previously detailed by Espinosa et al. (2012, 2014).

2.3. Ethnobotanical data collection

Ethnobotanical study was conducted in all the seven municipals that constitute Valley of Juruena Region. Valley of Juruena area was visited 20 times between 2010 and 2013. One informant per family who was atleast 18 years of age and had been living more than a year in the study area was selected for the interview. Interviews were conducted using a detailed form to obtain sociodemographic and ethnobotanical data. A free list technique was used, in which informants were asked to list the medicinal species that they knew and/or used. The informants were also asked to describe the methods of preparation of the plant, part used, therapeutical indication, dosage and duration of application, including descriptions of side-effects or perceived toxicity or caution measures applied to avoid toxic effects.

Most plant species were collected together with the informants and in some cases; plants were collected in a later visit in the same location where the informant lived. As shown in Table 2, emic perceptions of the illnesses as reported by the informants (use-report, UR) were used for the purpose of comparison and to analyze the cultural importance.

The interviews were conducted in the local language 'Portuguese' and the documentation of the data in the field was also done in the same local language, in addition to voice recording for later verification.

During the three years of field-research, 1123 specimens of vascular plants were collected. Plants were pressed in the field and prepared for identification. The system used for species classification was the Angiosperm Phylogeny Group III (APGIII). The scientific names and the distribution of the species were confirmed with the databases of the Missouri Botanical Garden (MOBOT) (available at <http://www.tropicos.org>), while the geographical origin status was based on Rio de Janeiro Botanical Garden database of list of species of the Brazilian flora (available at <http://floradobrasil.jbrj.gov.br/>). Vouchers that were collected in the flowering state and/or with fruits were identified by comparison with the specimens at the Herbário UFMT (Universidade Federal de Mato Grosso). Herbarium vouchers were also incorporated in the respective collections of the following herbaria for identification: Herbário UFMT, Cuiabá campus, HERBAM Southern Amazon, State University of Mato Grosso (UNEMAT), Alta Floresta Campus and CGMS/MS Campo Grande. The curators of these herbaria, whose name are Germano Guarim Neto, Célia Regina Araujo Soares Lopes and Joana Pott, respectively, did the identification. APG III classification system was employed (The Angiosperm Phylogeny Group, 2009). The voucher number of each plant identified is included in Table 1.

Table 2

Quantitative ethnobotanical analysis of the 12 categories of indigenous uses of Valley of Juruena, Mato Grosso, Legal Amazon, Brazil.

Category of indigenous uses (group of illness)	ICF	Use-report	% Ur _{tot}	Taxa	% Taxa	% Leaf/aerial part	% Root/tuber	% Bark

Different uses (DU)	NA	641	16.17	145	42.31	NA	NA	NA

Total number of use-reports is 3973; total number of taxa is 332; ICF, informant consensus factor; % Urtot, percentage of use-reports that contributed to the total amount of use-reports by the respective illness category; Taxa, total amount of plant species contributing to the use-reports of the respective illness category; % Taxa, percentage of the plant species reported for an illness category with respect to the total amount of reported plants species ; % Bark, percentage of use-reports for the respective illness category which indicate barks; % Leaf/aerial part, percentage of use-reports for the respective illness category that indicate leaves or aerial parts; % Root/tuber, percentage of use-reports for the respective illness category which indicate roots or tubers.

2.4. Data analysis

The ethnobotanical data were evaluated through the quantification of UR, and the informant consensus factor as described by Trotter and Logan (1986). Additionally we evaluated the most important medicinal plants of this region using published literature on the phytochemistry and pharmacology of these species as similarly reported by Leonti et al. (2001).

2.4.1. Informant consensus factor (ICF)

The ICF (Trotter and Logan, 1986) was calculated according to the following formula: $ICF = \frac{Nur - Nt}{Nur} / Nt - 1$. Where Nur refers to the number of use reports of informants for particular illness category, and Nt is the number of species used for particular illness by all informants. The ICF reflects the homogeneity of the information and consensus between the informants (Gazzaneo et al., 2005). This factor ranges from zero to one, where increasing values indicate high rate of informant consensus. The ICF is used to show cultural coherence in the selection of certain medicinal plants or agents employed in the treatment of a certain illness category, and seem to highlights their effectiveness in treating a particular disease (Heinrich et al., 1998; Leonti et al., 2001).

2.4.2. Literature review

Data search was performed using the following electronic databases: Pubmed, SciFinder, Chemical Abstracts, Biological Abstracts, Web of Science, Science Direct and SciELO, the collection of libraries of Osvaldo Cruz Foundation and Botanical Garden – RJ as well as books on botany and pharmacology. Searches were carried out using the keywords: "scientific name of the plant family" and "vernacular name".

Scientific names and abbreviations of authors of taxa are in accordance with the Brazilian Flora Species List, International Plant Name Index, the TROPICOS database and Missouri Botanical Garden. The botanical terms are according to Judd et al. (2002) and Pereira and Agarez (1977).

For the purpose of further discussion on phytochemical and pharmacological of literature findings, we selected for review species within a use-category with at least 200 URs and an ICF of at least 0.7. For each of the use-category, only plants native to or naturalized to Brazil with the highest UR per category were selected.

We excluded discussion of exotic plants that have been extensively studied and are well documented in the literature, because discussing these plants will make the paper superfluous.

2.5. Ethical aspects

The project was approved by the Ethics Committee on Research involving Human Subjects in November 2010, under the Protocol no. 958/CEP-HUJM/2010 and the National Board of Genetic Heritage of the Ministry of Environment (CGEN/MMA), under Resolution no. 247 published in the Brazilian Official Gazette, in April 2013. The access to samples (plants parts) of Genetic Patrimony was authorized by Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq), under No. 010728/2013-9 (Table 2).

3. Results and discussion

3.1. Demographic characteristics of informants

Of the 393 informants who responded to the form, the largest proportion was female (68.7%), predominantly in the age range of 40 and 59 years (41.8%). A greater proportion of respondents were from the South, Southeast and Northeast of Brazil (79.6%), with only 4.8% born in the Valley of Juruena Region. Around 87% of the respondents had been living in the Region for more than five years. Analysis of how respondents' came to acquire the use of medicinal plants shows that 79.79% (291) of the respondents learnt it from their family members (Fig. 2A).

When asked for the reasons for using herbs, 45.48% (167) of the respondents said that they learnt it principally because it is part of their cultural tradition, while another 33.97% (125) does so because of the perceived safety (Fig. 2B). These informations showed the importance of tradition and family influence in the transmission and preservation of traditional medicine knowledge.

According to Alexiades (1996), the most reliable medicinal uses are those already used by the informants, relatives or acquaintances of the same. Apparently, those without formal education seem to be more knowledgeable of medicinal plants than those who had some formal education. For example, 35 respondents who had less than one year of schooling contributed 411 UR (10.34% of the total reports) compared to 61 of those who had between 1 and 9 years of schooling, but contributed 394 (9.91%) UR. Similar results have been reported in studies conducted in Ethiopia (Gedif and Hahn, 2003; Giday et al., 2009) and Thailand (Wester and Yongvanit, 1995). The monthly income of the majority was between US\$ 242 and \$ 1210, which corresponds to one and five times the Brazilian minimum wage (81.2% of respondents).

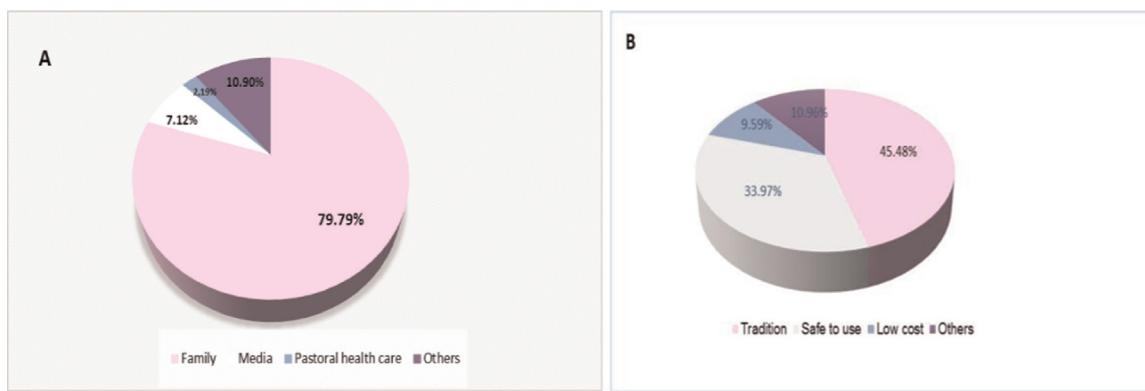

Fig. 2. (A) Sources of the informants knowledge on medicinal plants. (B) reasons for using medicinal plants by the informants.

3.2. Medicinal plants and associated knowledge

The respondents from Valley of Juruena cited 332 plants as being used for medicinal purposes. However, only 271 were identified by the botanists attached to the herbaria and another 61 by the first author using books (Corrêa and Penna, 1984; Guarim Neto, 1996; Lorenzi and Matos, 2002) (Table 3).

Analysis of the contribution of the municipals to the URs shows that Colniza municipality accounts for the higher percentage (38.30%) with 1371 UR, followed by Juína 830 UR (20.89%) and Aripuanã with 708 (17.82%), based on the proportion of informants interviewed. Out of 393 informants, 365 (93.0%) reported using medicinal plants in self-care, with a maximum of 86 UR reported by a woman and a maximum of 81 UR reported by a male. In total, we obtained 3973 UR associated with 332 different plant species belonging to 93 botanical families and 277 genera (Table 3). Plants used to treat gastrointestinal disorders were the most frequently reported (21.12% of UR) followed by respiratory complaints (20.59%), fever and aches (10.60%), diseases of the skin (10.09%) and genitourinary problems (8.73%).

Concerning the number of taxa noted in this survey and in the order of decreasing magnitude of the most cited, they are GA (157), DU (137), FI (127), RE (108), GU (81) and GY (67). This is a highly significant number of taxa when compared with other ethnobotanical surveys conducted in the Legal Amazon area of Mato Grosso (Van Den Berg, 1982; Vieira, 1992; Guarim Neto, 1996). Ninety three (93) plant families were recorded. Asteraceae 12.67% (29 species), Fabaceae 9.28% (24 species) and Lamiaceae 9.34% (22 species) topped the list of plant families with the highest citations.

Out of the recorded species, 64.45% were native, 42.42% were herbaceous and 32.72% were trees. The most common methods of preparations were infusion (45.70%) followed by decoction (23.41%). The parts of the plants used were leaves (64.50%), roots (8.90%) and bark (7.84%), while fruits, seeds, flowers as well as oils, latex and resins account for the remaining 18.76%.

As can be seen in Table 2 the ICFs for the use-categories are relatively high, suggesting exchange of informations or common knowledge among the population of Valle do Juruena on medicinal plants or apparent efficacy of these plants. This may be related to the mode of transmission of the information in this population (mainly through parents) and/or because the informants sampled had lived for a considerable period (more than 5 years) in this Region.

3.3. General analysis of the data

High UR and ICF values were obtained for fever and headaches (UR=405; ICF=0.68), diseases of the skin (UR=400; ICF=0.76)

and genitourinary related complaints (UR=335; ICF=0.74). As we stated above, it may be due to the common occurrence of these conditions due to the nature of economic activities, health and sewage facilities of these inhabitants of the area under study. A relatively high URs and ICF was also obtained for the women's health use-category (UR=248; ICF=0.75).

In some of these use-categories, there is prominence of some well known exotic plants, like in the case of gastrointestinal disorders (*Mentha × piperita* and *Bidens pilosa* L., 40 and 32 UR respectively) and skin diseases [*Aloe vera* (L.) Burm, 50 UR]. As Leonti and Casu (2013) noted, the present globalization is currently accelerating the interchange between local and global pharmacopoeias through international business interests, the print media, television, the World Wide Web, and thus generating a feedback loop. However, it is unlikely that these factors are responsible for the sizeable portion (22.13%) of the exotics encountered in this study, since negligible number of the informants reported acquiring information on medicinal plants through mass media or the internet, while majority did so through their family members and by traditional practices (Fig. 2).

The readers may also consult a prime work by Bennett and Prance (2000) on plants introduced to Southern America. These authors also observed that most of the exotics introduced are used in the treatments of respiratory and skin problems. According to these authors, some of the primary reasons advanced for the introduction of plants might relate to their use as food ingredients (such as seasoning and coloring purposes), in this case we may cite *Mentha × piperita* and for their well known therapeutic purposes like in the case of *A. vera*.

As noted in our study, the most common exotic plants employed in many use-categories have been extensively studied and are frequently encountered in many studies of this nature in many communities either as exotics or natives (AbouZid and Mohamed, 2011; Juárez-Vázquez et al., 2013; Savikin et al., 2013). *B. pilosa* L. is another commonly encountered exotic plants. *B. pilosa* is a globally distributed across temperate and tropical regions. The folkloric use of *B. pilosa* has been recorded in America, Africa, Asia and Oceania (Bartolome et al., 2013).

Culture-bound syndrome (0.14), diabetes (0.40), skeleton-muscular ailments (0.57) had relatively lower values of ICF value.

Leaves and aerial parts of the plant are most commonly used, followed by root/tuber and then the bark in all use-categories, (see Table 1). The predominance of leaves in ethnomedicine of many tribal communities has been noted (Amri and Kisangau, 2012; Ayyanar and Ignacimuthu, 2011; Prabhu et al., 2014; Yabesh et al., 2014). This may be due to the ease of collection of leaves and their availability throughout the seasons when compared to the underground parts, flowers, fruits, etc. (Giday et al., 2009). And from the scientific point of view, leaves are active in photosynthesis and

Species distribution were assigned based on Missouri Botanical Garden database, available at www.tropicos.org, while geographical origin was based on Rio de Janeiro Botanical Garden database, available at <http://floradobrasil.jbrj.gov.br/>. Both databases were last accessed on the 14th of June 2015.

production of metabolites (Ghorbani, 2005).

The most common forms of preparations of the herbal medicines were infusion (45.70%) and decoction (23.41%). We discuss in the following section the phytochemical and pharmacological review of plants selected based on cultural use importance.

3.4. Literature survey and discussions on the selected species of most cited in each use-category

3.4.1. Gastrointestinal disorders

Baccharis crispa Spreng popular known in Brazil as ‘carqueja’ or ‘carqueja amargosa’ was the most cited native plant in this UR category with 57 UR. It is popularly known in Juruena region as “carqueja”. The leaves collected in the morning in the adult stage of the plant are usually employed in the form of infusion, but sometimes as maceration and decoction in alleviating symptoms of diabetes, skin itching, headache, gastrointestinal disorders (intestinal colic, diarrhea, indigestion, flatulence and others), malaria, inflammation and in weight loss treatment. As noted in this present work, similar uses of *B. crispa* have been reported including as a treatment or prevention against hepatic diseases, rheumatism and morbid obesity (Oliveira et al., 2005).

3.4.1.1. Pharmacological properties. Gamberini et al. (1991) for example, reported similar folkloric use of *B. crispa* and in addition, the authors demonstrated the antisecretory activity of the aqueous extract of the plant in pylorus ligated rats. The extract (1 g/kg, p.o.) also prevented gastric ulcers induced in rats by cold stress but not by indomethacin, supporting its use in ethnomedicine, at least partially, in the treatment of gastrointestinal disorders like gastric ulcer. Moreover, they also justified its use as an anti-diarrheal and anti-spasmodic, all of which further attest to its usefulness in treating gastrointestinal disorders. Oliveira et al. (2005) also demonstrated the anti-diabetic effect of the plant, albeit at a very high dose. However, all the pharmacological studies encountered are preliminary, further studies are warranted in this regard.

3.4.1.2. Phytochemical studies. Phytochemical studies by Simões-Pires et al. (2005) revealed the presence of mono caffeoyl ester derivatives of quinic acid Compounds 3-O-[E]-caffeoylquinic acid, 5-O-[E]-caffeylquinic acid, 4-O-[E]-caffeyl-1-methylquinic acid, 4,5-O-[E]-di-caffeylquinic acid, 3,4-O-[E]-dicaffeoylquinic acid and 3,5-O-[E]-di-caffeylquinic acid. The presence of quinic acid and its derivatives have been suggested to be responsible for many of its pharmacological activity (Matsingou et al., 2000), including gastric and esophageal injuries and inflammation (Gene et al., 1992; Oh et al., 2001).

3.4.2. Respiratory complaints

Mentha pulegium is an aromatic plant popularly known in Brazil as ‘poejo’ and commonly referred to as ‘Pennyroyal’ in English, originated from North Africa, Europe and western Asia, but it is widely naturalized in the Amazon, Cerrado and Atlantic forest of the phytogeographic regions of Brazil (Harley et al., 2014). It is commonly used in the form of decoction, infusion and sirup in treating a wide array of ailments with 94 UR, with main uses being for respiratory afflictions (70 UR) and to a lesser extent gastrointestinal (6 UR), fever and headache ailments (9 UR). These uses have been traditionally documented in similar study by our group as well as from other countries (Bieski et al., 2012; Gürdal and Kültür, 2013).

3.4.2.1. Pharmacological properties. The *in vivo* and *in vitro* antibacterial activities of various extracts or essential oils of *M. pulegium* have been documented (Cherrat et al., 2014; Erhan et al., 2012; Khaled-Khodja et al., 2014; Mahboubi and Hagh, 2008; Nikolić et al., 2014; Selim et al., 2013; Teixeira et al., 2012) and

antifungal activity (Nikolić et al., 2014). The plant has long been used, and as an abortifacient is known to be hepatotoxic (Anderson et al., 1996). In addition, its neurotoxicity effect has also been reported (Bakerink et al., 1996; Sztajnkrycer, 2003). However, in the form that it is used traditionally, it is not likely to cause toxicity.

3.4.2.2. Phytochemical studies. Chemical studies on *M. pulegium* have revealed the presence of phenolic acids, flavonoids, terpenoid phenols and terpenic acids, essential oils with elevated pulegone content (33.65%) (Cherrat et al., 2014). The essential oil of *M. pulegium* from different parts of the world always contains pulegone in varying amounts (Nikolić et al., 2014; Zwaving and Smith, 1971). The toxic principle in *M. pulegium* is the R-(+)-pulegone which is metabolized via hepatic cytochrome P450 to toxic intermediates (Anderson et al., 1996; Bakerink et al., 1996; Sztajnkrycer, 2003).

3.4.3. Fever and aches

Arrabidaea chica (Humb. & Bonpl.) B. Verl. (syn. *Fridericia chica* (Bonpl.) L.G. Lohmann) is a vine belonging to the Bignoniacae family. The species is native to the Amazon region, where it is called “pariri”, “crajiru”, “carajuru” or “crajiru” and it occurs throughout the tropical regions of South America and Africa. As observed in this study a total of 97 UR for this medicinal plant were obtained for 9 UR. It is employed in the treatment of genitourinary complaints (28 UR), women's health complaints (16), fever and pains (28 UR) and rheumatism (8 UR). However, the highest UR of this plant was in the FI group, and it will therefore be discussed in this use-category. This present result corroborates previous studies that reported its widespread use as a medicinal plant especially in the Amazon region (Barbosa et al., 2008; Bieski et al., 2012; Lorenzi and Matos, 2002; Mafioleti et al., 2013).

3.4.3.1. Pharmacological properties. Due to the widespread use of *A. chica* in ethnomedicine, it has been subject of various pharmacological and biological studies to verify experimentally its ethnomedical use. Extracts and fractions from the leaves of *A. chica* have been shown to possess different activities supporting its traditional uses. The activities include among others, hepatoprotective (hydroethanolic extract), antimicrobial (hydroethanolic and dichloromethane extracts), wound healing (methanolic and ethanolic extracts), anti-inflammatory (aqueous extract), analgesic, anti-helminthic and anti-Leshmania activities (hexanic extract) (Barbosa et al., 2008; Höfling et al., 2010; Mafioleti et al., 2013; Paula et al., 2014; Rodrigues et al., 2014). Recently also the ethanol and aqueous extracts of *A. chica* were shown to be anti-inflammatory, antiangiogenic and antiproliferative activities in a murine model (Michel et al., 2015).

3.4.3.2. Phytochemical studies. *A. chica* has been subjected to intense phytochemical studies from decades as indicated by the work of Chapman et al. (1927) and in a subsequent study by Takemura et al. (1995) where the author detected flavonoids, anthocyanins, tannins and phytosterols. A flavone, 7,4'-dihydroxy-5-methoxyflavone was later isolated by Takemura et al. (1995). The principal components of anthocyanins found in *A. chica* were later confirmed by subsequent studies (Paula et al., 2013, 2014) and that they are of type 3-desoxyanthocyanidins, namely 6,7,3'-trihydroxy-5-dimetoxyflavil- avilium and 6,7,3',4'-tetrahydroxy-5-methoxyflavilium, known as carajurone and carajurin respectively. Luteolin, a 3',4',5,7-tetrahydroxyflavone and quercetin presence have also been reported (Eda et al., 2002; Hirano et al., 2001; Seelinger et al., 2008). In addition, isoscutellarein, 6-hydroxyluteolin, hispidulin, scutellarein luteolin, and apigenin have been reported from this plant, while 4'-hydroxy-3,7-dimethoxyflavone, vicenin-2 and

kaempferol have been isolated from its leaves (Barbosa et al., 2008; Siraichi et al., 2013). There are reports of the anti-inflammatory, anti-allergic, and anti-tumor properties of these compounds in the literature (Eda et al., 2002; Hirano et al., 2001; Seelinger et al., 2008).

3.4.4. Diseases of the skin

Alternanthera brasiliiana (L.) Kuntze belongs to Amaranthaceae; it is a herb indigenous to Brazil and is popularly called “terramicina” (teramicine) “penicilina” (penicillin), and “perpétua-do-mato” and is employed as an ornamental plant as well (Macedo et al., 1999). It is widely distributed in the Amazon, Caatinga, Cerrado (Savannah like) and Atlantic forest of the phytogeographic regions of Brazil (Senna, 2014). It is reportedly employed in the present study, principally in the treatments of skin afflictions (71 UR), respiratory ailments (12 UR) (for both infections and inflammation) and genitourinary ailments (8 URs). Similar uses as well as its use in against, cough, diabetes, diarrhea, analgesic and inflammation, have been reported in previous studies (Formaggio et al., 2012; Kumar et al., 2011, 2014).

3.4.4.1. Pharmacological properties. Several biological and pharmacological activities of the plant have been documented. These include wound healing, antibacterial, analgesic, anti-inflammatory activities, and anti-herpes-simplex-virus activity (Baru et al., 2012; Barua et al., 2013; Kumar et al., 2011, 2014; Trapp et al., 2014).

3.4.4.2. Phytochemical studies. A phytochemical study of the leaves extract of *A. brasiliiana* demonstrated the presence of flavonoids, triterpenoids, principally the derivatives of kaempferol and quercetin (Kumar et al., 2011). In a study of the essential oil of its leaves, 25 compounds were identified (Facundo et al., 2012; Wakabayashi et al., 2010). More recently, Wakabayashi et al. (2010) identified three flavones. The pharmacological and biological activities of the plant have been attributed to some of these constituents.

3.4.5. Genitourinary problems

Phyllanthus niruri popularly known as “quebra-pedra” (‘stone-breaker’), belongs to the Euphorbiaceae family and is indigenous to the Amazon rainforest and other tropical areas, including South East Asia, Southern India and China but it has a worldwide distribution (Girach et al., 1994). It is found in the Amazon, Caatinga, Cerrado (Brazilian Savannah) and Atlantic forest phytogeographic regions of Brazil (Secco et al., 2014). It is popularly used in the current study almost entirely in the treatment of genitourinary afflictions with 45 out of 48 UR.

There are several reports on the usefulness of *P. niruri* in the alleviation of diverse ailments such as fever, diarrhea, colic and kidneys, as diuretic, urolithiasis, excess uric acid and as an expectorant (Boim et al., 2010; Bagalkotkar et al., 2006; Perry and Metzger, 1980). It is an important medicinal plant widely used in ayurvedic preparation of various formulations (Chatterjee and Sil, 2007).

3.4.5.1. Pharmacological properties. Several of these claims have been validated using *in vitro* and *in vivo* studies and clinical studies in humans. The *in vitro* and *in vivo* pharmacological, biochemical, and clinical studies carried out on the extracts, and the main active constituents isolated from *P. niruri* (Vimala and Gricilda Shoba, 2014; Bieski et al., 2012; Boim et al., 2010; Bagalkotkar et al., 2006; Murugaiyah and Chan, 2006).

There are reports in the literature demonstrating its pharmacological properties such as hepatoprotective (Calixto et al., 1998), anti-viral, especially against hepatitis B virus (Liu et al., 2014), antibacterial and analgesic (Amin et al., 2013).

Clinical investigations revealed that *P. niruri* does not present acute or chronic toxicity, and preliminary data indicates that the extract promotes the normalization of calcium levels in patients'

hypercalciuria (Nishiura et al., 2004), thus demonstrating its usefulness in some types of genitourinary ailments.

3.4.5.2. Phytochemical studies. More than 50 compounds have been identified in the *P. niruri*. The major different classes of organic compounds with various medical interest reported, are the lignans, tannins, polyphenols, alkaloids, flavonoids, terpenoids and steroids. Readers may consult excellent reviews and research articles on this topic from the cited references (Narendra et al., 2012; Boim et al., 2010; Bagalkotkar et al., 2006; Murugaiyah and Chan, 2006; Calixto et al., 1998).

Majority of the compounds or classes of compounds isolated or detected in *P. niruri* have been correlated to its ethnomedical uses. The triterpenes for example have been found to inhibit the cytotoxicity induced by calcium oxalate, including a reduction in the excretion of stone forming constituents and crystal deposition markers in the kidneys (Barros et al., 2003; Boim et al., 2010).

3.4.6. Women's health

Gossypium barbadense Linn (family Malvaceae) is a perennial under shrub 1–3 m high, native to South America. It is mainly employed in the present survey in the treatment of uterine inflammation (44 UR) and less frequently for infections of the urinary tracts and kidney, in the form of infusion, decoction and maceration. Principally, the dry or fresh leaves are commonly employed in the preparations, but also to a lesser extent are the roots, flowered parts and the seeds. Similar reports of its uses in treating female health problems have been related, particularly in treating uterine hemorrhage and regulation of menses (Ososki et al., 2002; Van Andel and Carvalheiro, 2013). In the literature, it has many ethnomedicinal uses, but of interest to this work is its uses in the treatment of venereal diseases and urethral discharge (Berkhill, 1985; Bieski et al., 2012; Ogunmefun and Gbile, 2012).

3.4.6.1. Pharmacological properties. The antimicrobial activity of the plant has been demonstrated in some studies (Essien et al., 2011; Luciano-Montalvo et al., 2013). To the best of our knowledge, there are no studies on the anti-inflammatory effect of *Gossypium barbadense* on the uterine or other animal models of inflammation, nor are there any studies that addressed its use in the treating or managing of women's ailments mentioned in this study, thereby constituting a potential prospect for future studies. The only confirmed pharmacological effect was on the blood-pressure-lowering effect of its leaves decoction (Hasrat et al., 2004). It will be interesting therefore, to carry out test using experimental models to verify the ethnomedicinal use of the plant.

3.4.6.2. Phytochemical studies. A number of bioactive triterpenoid and sesquiterpenoid aldehydes compounds have been isolated and characterized from *G. barbadense* (Essien et al., 2011).

3.4.7. Skeleto-muscular disorders

Solidago microglossa DC. is popularly known in Brazil as “arnica-brasileira”, “arnica,” “arnica-do-mato,” “arnica-silvestre,” among others (Lorenzi and Matos, 2002; Bieski et al., 2012). It belongs to the Asteraceae family and is indigenous to Brazil. It has about 10 synonyms. It is found in the Brazilian phytogeographic domains of Caatinga, Cerrado, Atlantic Rainforest and Pampa (Borges and Teles, 2015). Its use reports in the study includes mainly skeleto-muscular complaints (8 UR), dermatological complaints (10 UR) and respiratory ailments (11 UR). The uses attributed to it according to literature include treating rheumatic and lumbar pain, contusions, wounds, inflammation, pain and uterine inflammation (Lorenzi and Matos, 2002; Bieski et al., 2012).

3.4.7.1. Pharmacological properties. *In vivo* experimental assays have shown that crude extracts of *Solidago microglossa* possess

local and systemic anti-inflammatory and analgesic effects in some animal models (Rocha, 2006; Goulart et al., 2007; Liz et al., 2008; Tamura et al., 2009). The wound healing of the plant has also been scientifically investigated and supported in animal models (Neto et al., 2005). A clinical study evaluating its efficacy in the treatment of lumbago showed that it produced a better effect than the placebo (da Silva et al., 2010).

It is also interesting to note similarities in the pharmacological spectra of actions of this plant and *Arnica montana*, from whose name other ‘arnicas’ mentioned in this study are popularly called. The anti-inflammatory and analgesic activities among others of *A. montana* is well known (Šutovská et al., 2014). To the best of our knowledge there is currently no pharmacological study on the other Brazilian ‘arnica’, *Pseudobrickellia brasiliensis* referred to here as arnica-do-mato.

All the aforementioned studies lend credence to the traditional use of this medicinal plant.

3.4.7.2. Phytochemical studies. Several phytochemical compounds have been detected and isolated from different parts of this plant. Therapeutic effects for a number of these compounds have been established and linked to their traditional use (Tamura et al., 2009). These include caffeoylquinic acid derivatives, the flavonoid rutin, carotenes, diterpenoids, flavonoids, glycosides, saponins essential oils just to mention but few (Hirschmann, 1988; Tamura et al., 2009; da Silva et al., 2010). Several studies have demonstrated the anti-inflammatory, wound healing and antimicrobial effects of many of these compounds (González-Gallego et al., 2010; Jin et al., 2010; Pan et al., 2010; Pelzer et al., 1998; Ríos and Recio, 2005; Verri et al., 2012).

3.4.8. Diabetes

Bauhinia forficata L. is popularly known as “pata-de-vaca” which means “cow’s foot”, because of the characteristic aspect of its bilobed leaves (Marques et al., 2013). It belongs to the Fabaceae family and is a plant indigenous to Brazil. The main use of the plant in the present survey was largely for the treatment of diabetes (9 UR), in addition to treating kidney infections (4 UR) in the form of infusion and maceration. The ethnomedical use of *B. forficata* in literature as diuretic, tonic, blood depurative, combating elephantiasis, control of hypoglycaemia and to reduce glycosuria (Ferreres et al., 2012).

3.4.8.1. Pharmacological properties. Pharmacological studies have been carried out on the leaf extracts (aqueous and alcoholic) in order to verify the antidiabetic activity in different *in vivo* models (Cunha et al., 2010; Menezes et al., 2007; Pepato et al., 2004, 2002, 2010). *B. forficata* is one of the most commonly used plants against diabetes (Filho, 2009). The therapeutic potential of this plant was first confirmed in 1929, with the clinical studies of Juliani (1929) which demonstrated the blood sugar lowering effect of *B. forficata*. The antidiabetic potential of the plant was subsequently, confirmed in dogs, humans and rabbits (Juliani, 1931, 1941). The reader may consult an excellent review by Filho (2009) on this species for further details, because reviewing this plant will make the present paper too voluminous.

3.4.8.2. Phytochemical studies. There are numerous studies on the chemical composition of the *B. forficata* leaves which confirm the presence of alkaloids, flavonoids, mucilages, essential oils, catechols, cyanogenic glycosides, steroids and tannins (Pepato et al., 2004; Silva et al., 2012). Duarte-Almeida et al. (2004) observed the presence of monoterpenes, and in significant quantities, β-caryophyllene present in the essential oil. Flavonoids, free and glycosylated, especially kaempferolic glycosides and quercetins account for the main constituents of *B. forficata* (Cunha et al., 2010; Marques et al., 2013). The mimetic effect like insulin of

Kaempferol-3-neohesperidoside has been shown in both *in vitro* and *in vivo* studies (Cazarolli et al., 2009). In addition, the promising hypoglycemic properties of kaempferitin have also been reported (Trojan-Rodrigues et al., 2012).

3.4.9. Culture-bound syndromes

In this group of illnesses, only eight UR were noted in this study. The plants that cited are *Ruta graveolens* (6 UR) and *Abelmoschus esculentus* (2 UR). These plants are reportedly used to cure what is locally called ‘mal olhado’ or ‘quebrante’ which simply means ‘evil eye’ and ‘brokennes’. The two are basically the same or related (Nery, 2006). We found a low consensus (ICF=0.14) in this group of plants. This appears to be typical for this group of illnesses as similar results have been obtained by other researchers in other cultures (Leonti et al., 2001).

In medicine and medical anthropology, a culture-specific syndrome or culture-bound syndrome is a combination of psychiatric and somatic symptoms that are considered a recognizable disease only within a specific society or culture. There are no objective biochemical or structural changes in the body, and the disease is not recognized in other cultures (Carel and Cooper, 2010).

‘Evil eye’ for example, seems to be a culture-bound syndrome that is common in the Latin America (Gallagher and Rehm, 2012; Gutiérrez et al., 2014). In addition, it is interesting to note that many of these cultural syndromes are widespread in rural populations of the world (Estomba et al., 2006). ‘Religious plants’ concept is generally believed to have begun in the initial stage of the human society (Sebastian and Bhandari, 1984; Sharma et al., 2012). However, it seems that the purpose to which the plants are used is more important than the plants itself and hence the low ICF that is usually obtained for these group of emic illnesses.

3.4.10. Venomous animals

Jatropha elliptica (Poh) Oken.

3.4.10.1. Pharmacological properties. *J. elliptica* (Pohl) Müll. Arg. (Euphorbiaceae) is a plant native to Brazil popularly called ‘batatapurga’. *J. elliptica* is a plant of the Euphorbiaceae family. It is an annual shrub herb that is distributed throughout the north and west of Brazil and has been reported to possess several medicinal properties (Corrêa and Penna, 1984).

Its root or rhizome in the form of decoction or maceration is used in the treatments of snake bites (5 UR) and blood depurative (1 UR). It is the only plant reportedly used in this study as anti-venom. *J. elliptica* is also used in ethnomedicine for the treatment of neoplasia, inflammation, ulcers and diuretic among others (Dos Santos and Sant’Ana, 1999). In addition, literature search shows that *J. elliptica* in the forms of maceration and infusion of its rhizome is used in the treatment of most severe itching, anti-syphilis, jaundice, rheumatism, amenorrhea, dropsy, tumors and snake bites (Corrêa and Penna, 1984; Duke, 1985).

In a study by Vilar et al. (2007) *J. elliptica* extract showed no neutralizing effect on the lethality of *Bothrops jararaca* venom in mice inoculated with the snake venom.

3.4.10.2. Phytochemical studies. Fractionation and purification of *J. elliptica* extract obtained from its rhizome furnished jatropheone and a mixture of jatropholones A and B, as the main compounds (Dos Santos and Sant’Ana, 1999). Various other constituents have been isolated from its rhizomes such as ferulic acid ester of the fraxetin coumarin, coumarin lignoide propacin, the triterpenoid acetyl-3-O-aleuritolic acid, a mixture of β-sitosterol and stigmasterol steroids (Santos et al., 2014) and a substituted pyridine pentahydrate, called diethyl-4-phenyl, 2,6-dimethyl-3,5-pyridinedicarboxylate (Marquez et al., 2005).

3.4.11. Different uses

Cymbopogon citratus (DC.) Stapf is popularly referred in Brazil as ‘capim-cidreira’ or ‘capim-limão’ and lemon grass in English. It

is widely naturalized in the Amazon, Cerrado and Atlantic forest of the phytogeographic regions of Brazil (Filgueiras, 2014). In the present study *C. citratus* is the most cited plant in the different use-categories (104 UR) and is most employed as an anxiolytic (57 UR) followed by alleviation of blood hypertension symptoms (17 UR). It gives a pleasant aroma after infusion, and is well known and used in tropical and subtropical countries as an antidepressant among other uses (Soares et al., 2013).

3.4.11.1. Pharmacological properties. Blanco et al. (2009) demonstrated the sedative/hypnotic properties of the essential oil obtained from the fresh leaves of *C. citratus* and scientifically validate its ethnopharmacological use in this regard, confirming the hypnotic, anxiolytic and anticonvulsant activities of the plant essential oil in experimental animals. Further studies by Costa et al. (2011) suggested that the anxiolytic-like effect of the essential oil is mediated by GABA-benzodiazepine receptor complex and demonstrated the dose-related hypotensive effect of *C. citratus* in experimental rats. In addition, the plant is also known for its antifungal, antimicrobial, anti-inflammatory, antioxidant, cancer-chemopreventive, antidepressive, and diuretic, sedative and analgesic (Tavares et al., 2014).

3.4.11.2. Phytochemical studies. Phytochemical analysis of different leaf extracts of *C. citratus* revealed the presence of tannins, phenolic acids, flavonoid glycosides, alkaloids and steroids (Soares et al., 2013). In a study, the following compounds were isolated from the methanol, MeOH/water, infusion, and decoction extracts of the plant: isoorientin, isoscoparin, swertiajaponin, isoorientin 2'-O-rhamnoside, orientin, chlorogenic acid, and caffeoic acid (Rahim et al., 2013).

There is active research in analyzing the essential oil obtained from the plant due to its extreme usefulness as medicinal, as well as in food and cosmetics applications. In a study of its essential oil, geranil (48.1%), neral (34.6%) and myrcene (11.0%) were the major constituents. In other studies, the authors concluded that citral was the principal constituent of its essential oil (Barbosa et al., 2008; Moore-Neibell et al., 2012).

4. Conclusions

This study represents an important step in the documentation and preservation of popular knowledge on medicinal plant use of the population of Valle do Juruena, by enabling identification of several species of principally native medicinal plants, and predominance of their uses in the region of Valley of Juruena. This demonstrates the rich cultural diversity of the region, even though the informants are not part of traditional communities but it reflects the heavy influence of the traditional culture in the appreciation of medicinal flora of the Legal Amazon of Mato Grosso and its environs. This constitutes one of the important steps towards preservation of traditional and ethnomedical knowledge of this region.

We would like to draw readers' attention to the use of *M. pulegium* in plant ethnopharmacy, due to its potential nephro- and neurotoxicities, even though it is widely used in many parts of the world.

There are several concordances on medicinal plants use among the seven municipals of the Valle do Juruena. We also found that several species cited in these municipals have also being related from other regions of Brazil and some in other parts of the world.

The values of ICF obtained for the categories reported indicate the degree of shared knowledge for the treatment of diseases with medicinal plants. The use-categories with the highest ICFs were for remedies related to the respiratory system (0.85) and gastrointestinal disorders (0.81). The number of URs for these 2 use-categories was also high. This may be explained by the fact that the communities surveyed are agrarian-based and therefore these diseases are typical of similar communities (Leonti et al., 2001;

Williamson et al., 2015). The high URs therefore seem to mirror the health situations of most of the municipals under study, because the leading causes of hospital admissions are infectious and parasitic diseases, respiratory diseases, circulatory system and genitourinary tract diseases (Mato Grosso, 2012).

In the case of gastrointestinal disorders, given the status of sanitary facilities, with most municipals lacking public sewage disposal system and most communities depending on the use of cesspool, there is higher possibility of contracting gastrointestinal related diseases. In most of these municipals, there are no private clinics or hospitals and very few Government hospitals, few laboratories to assist in diagnosis of diseases and few health workers available to service the population.

Valle do Juruena's ethnomedicine flora is being threatened by factors such as grazing, expansion of new agricultural land and deforestation, in particular unsustainable use of native medicinal trees, making untenable the purpose of generating income with sustainable use.

The ethnobotanical survey is not only a good way to document the knowledge of medicinal plants before their disappearance, but also a key step for further investigations. Therefore, immediate action, particularly in combating deforestation, with more surveillance should be taken to ensure the conservation and preservation of the plant flora and local ethnoculture.

Comprehensive programs for the conservation of traditional knowledge of medicinal plants are needed, like the 'Farmacia viva Program' of Brazil and production of guidebooks on the correct use of these plants, among others. As has been stated earlier, that ethnobotany/ethnopharmacological survey is one of the most viable ways of developing new therapeutic agents, the current study shows that plants highly valued by these communities have been scientifically confirmed in *in vivo* and sometimes clinical studies. However, there are more yet to be done to scientifically establish the use of some other indications of these plants. Finally, these data could also serve as a basis for biodiversity conservation and community development.

Acknowledgments

The authors thank all the informants and staff members of Family Health Programme of the Valley of Juruena, for the assistance and contributions made throughout ethnobotanical fieldwork, Fundação de Amparo à Pesquisa de Mato Grosso (FAPEMAT Proc. no. 2059782011), Coordenação de Aperfeiçoamento de Pessoal de Nível Superior, (CAPES) for granting scholarships, the Botanist Prof. Dr. Germano Guarim Neto, UFMT. Instituto Nacional de Ciência e Tecnologia em Áreas Úmidas (INAU) and Conselho Nacional de Desenvolvimento Científico e Tecnológico (INAU)/CNPq/MCT (Proc. no. 704792/2009) for funding the research work.
